#### Introduction

- From a diagnostic and management perspective, leprosy is a complex tropical infection
- Patients who are affected by leprosy are at risk of several complications associated with the disease itself and its treatment
- Standard WHO multi-drug treatment (MDT) for leprosy consists of medications that are potentially harmful and cause a range of adverse systemic effects
- Alternative options for potential treatment have emerged such as monthly dosing of Rifampin-Ofloxacin-Minocycline (ROM) combination therapy, however, there is limited synthesized evidence of efficacy
- Multibacillary leprosy, characterized by many skin lesions and a high bacillary load, may be most amenable to a fluoroquinolone-based treatment protocol
- Monthly- or single dosing of ROM has emerged as a potential treatment option for leprosy, however, a synthesis of the evidence supporting ROM does not exist

## Methods

- Abstracts reporting the efficacy & safety of monthly ROM treatment in multibacillary leprosy in human patients were targeted using combinations of the search terms "ROM" & "Leprosy" from inception to May 11, 2022
- Non-English publications were included and translated using Google Translate
- During all phases of screening a tertiary arbitrator arbitrated any inclusion/exclusion discrepancies

Included	Excluded			
Systematic reviews	Review articles			
Randomized controlled trials	Case reports			
Clinical trials	Case series (n<4)			
Cohort studies	Editorials			
Observational studies	Conference proceedings			
Case-control studies	Animal studies			
Case series (n>5)	Trial descriptions only

	Range	33.33%	-	-	-	-	

**Table 4.** Preliminary Summary of Primary Outcomes

### Discussion

- Interim findings suggests that treatment failure and side effects are greater in the comparator group (+2.29% and +52% respectively), and that relapse is slightly greater in the ROM group (+0.94%). This suggests that ROM is slightly more efficacious than its comparator, however a more robust analysis is necessary
- Several determinants of health were identified qualitatively throughout this analysis including:
- Social environments 50% of non-adherent patients denied having leprosy due to potential loss of jobs and/or marriage prospects<sup>3</sup>
- Patient education 86% of respondents did not understand the concept of their disease<sup>8</sup> • Indicating a clear opportunity for bedside quality improvement
- Gender Women completed treatment at a rate of 65.6% and men at 79.2% (p<0.05)<sup>9</sup>
- Further investigation to better understand gender- and sex-based influences on treatment and prognosis warranted
- Synthesizing the current evidence discussing the efficacy of monthly ROM, will strengthen the current body of knowledge surrounding the treatment of paucibacillary leprosy, and may allow for the development of standardized fluoroquinolone-based treatment protocols.
